Отчет по лабораторной работе Программирование серверного и клиентского приложения прикладного протокола

> Работу выполнила: Кузовкина Е.О. Группа: 3530901/60202 Преподаватель: Зозуля А.В.

1. Задание

Разработать приложение—клиент и приложение—сервер банковского сервиса. Сервис позволяет пользователю открывать депозитные вклады, зарабатывать на процентах по вкладу, закрывать вклады.

2. Основные возможности

Серверное приложение должно реализовывать следующие функции:

- 1. Прослушивание определенного порта
- 2. Обработка запросов на подключение по этому порту от пользователей сервиса
- 3. Поддержка одновременной работы нескольких пользователей сервиса через механизм нитей
- 4. Прием запросов на:
 - а. открытие вклада с фиксированной прибыльностью 10% для владельца и 5% для банка;
 - b. пополнение вклада;
 - с. начисление процентов по вкладу для владельца и банка (отдельной командой, которую можно вызывать неоднократно);
 - d. состояние вкладов (для банка всех);
 - е. состояние баланса банка;
 - f. закрытие вклада с выплатой процентов.
- 5. Обработка запроса на отключение клиента
- 6. Принудительное отключение клиента
- 7. Выдача списка подключенных клиентов в формате:

№ п/п IP-адрес порт

Клиентское приложение должно реализовывать следующие функции:

- Установление соединения с сервером
- Передача запросов серверу
- Получение ответов на запросы от сервера
- Разрыв соединения
- Обработка ситуации отключения клиента сервером

3. Настройки приложений

Разработанное клиентское приложение должно предоставлять пользователю настройку IP-адреса или доменного имени сервера и номера порта, используемого сервером.

4. Методика тестирования

Для тестирования приложений запускается сервер и несколько клиентов. В процессе тестирования проверяются основные возможности приложений по передаче и приему информации, параллельная обработка запросов.

5. Прикладной протокол

5.1. Реализация

Сервер – программа, написанная на языке С, поддерживаемая работу с множеством клиентов. В программе задействованы следующие виды потоков:

• Основной

- создаёт сокет, принимающий новые соединения
- создаёт поток, принимающий соединения
- создаёт поток, слушающий пользовательский ввод

• Принимающий соединения

- принимает соединения от новых клиентов
- создаёт отдельный клиентские поток для каждого нового соединения
- добавляет подключенного клиента в список подключённых клиентов

• Слушающий консоль

- слушает пользовательские команды
- выполняет действия в соответствии с введённой командой

• Клиентский

- принимает пакеты от клиента
- обрабатывает принятые пакеты в соответствии с их типом

В программе присутствуют следующие типы структур:

- связный список для хранения информации о клиентах
- связный список для хранения депозитов

Клиент представляет из себя программу на языке С.

Она предоставляет пользователю выбор из нескольких действий (открыть вклад, посмотреть открытые вклады, пополнить вклад, закрыть вклад, посмотреть счет банка, либо завершить работу программы).

В соответствии с выбором пользователя формируется и отправляется на сервер пакет определённого формата, затем происходит приём и обработка ответа сервера.

6. Описание архитектур

6.1. Структура ТСР-клиента

Клиент протокола TCP создаёт экземпляр сокета, необходимый для взаимодействия с сервером, организует соединение, осуществляет обмен данными, в соответствии с протоколом прикладного уровня.

Типичная структура ТСР-клиента представлена на рис.6.1.

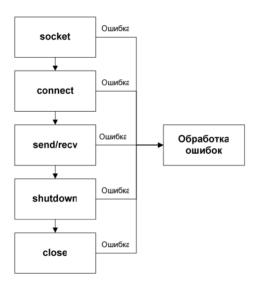

Рисунок 6.1. Типичная структура ТСР-клиента

Если инициатором разрыва соединения является клиентское приложение, то далее следует вызвать функцию shutdown и после этого закрыть сокет.

Каждый вызов функций библиотеки сокетов должен сопровождаться проверкой на наличие ошибочной ситуации и обработкой этой ситуации.

6.2. Структура ТСР-сервера

Организация ТСР-сервера отличается от ТСР-клиента в первую очередь созданием слушающего сокета (см. рис. 6.2 а). Такой сокет находится в состоянии listen и предназначен только для приёма входящих соединений. В случае прихода запроса на соединение создаётся дополнительный сокет, который и занимается обменом данными с клиентом.

Типичная структура TCP-сервера и взаимосвязь сокетов изображена на рис. 6.2 a) и б).

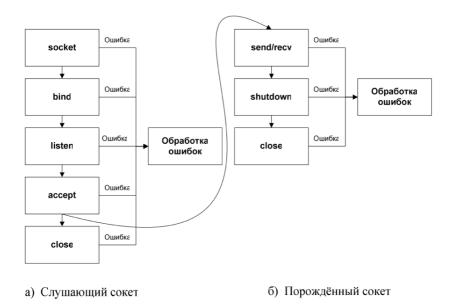

Рисунок 6.2. Типичная структура ТСР-сервера

6.3. Структура UDP-клиента

Структура UDP-клиента ещё более простая, чем у TCP-клиента, так как нет необходимости создавать и разрывать соединение. Варианты организации UDP-клиента изображены на рис. 6.3.

Наличие двух вариантов организации связано с возможностью в UDРприложениях использовать вызов connect, устанавливающий значения по умолчанию для IP-адреса и порта сервера.

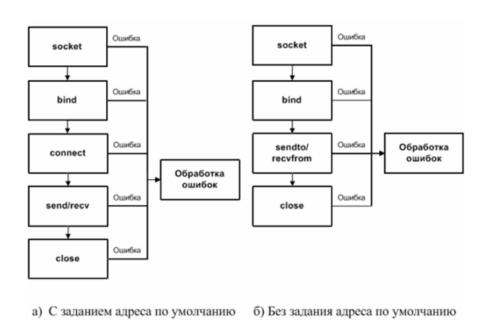

Рисунок 6.3. Типичная структура UDP-клиента

6.4. Структура UDP-сервера

Ввиду того, что в протоколе UDP не устанавливается логический канал связи между клиентом и сервером, то для обмена данными между несколькими клиентами и сервером нет необходимости использовать со стороны сервера несколько сокетов. Для определения источника полученной дейтаграммы серверный сокет может использовать поля структуры from вызова recvfrom. Типичный способ организации UDP-сервера приведён на рис. 6.4.

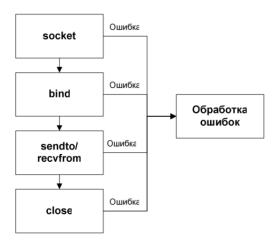

Рисунок 6.4. Типичная структура UDP-сервера

7. Особенности реализации сетевых и многопоточных приложений

Для чтения из сокета заданного количества байт использовался метод readn():

```
1
  int readn(int sockfd, void *dst, size_t len){
2
3
       int total_number_read = 0;
       int local number read;
4
5
       while (len > 0) {
6
           local number read = read(sockfd, (char*) dst + total number read, len);
7
8
           if (local number read = 0) {
9
               return total_number_read;
10
           }
11
12
           if (local_number_read < 0) {</pre>
13
               return local_number_read;
           }
14
15
           total number read += local number read;
16
17
           len -= local number read;
18
19
      return total number read;
20
```

Для контроля и завершения всех потоков использовался join. Ожидание завершения всех потоков:

```
pthread_join(accepting_thread, NULL);
pthread_join(console_listening_thread, NULL);
```

Для работы с разделяемыми ресурсами использовались мьютексы. Инициализация мьютексов:

```
1 init_list_of_clients_mutex();
2 init_list_of_deposits_mutex();
```

Код требующий использования разделяемых ресурсов:

```
pthread_mutex_lock(&list_of_clients_mutex);
pthread_mutex_unlock(&list_of_clients_mutex);
pthread_mutex_lock(&list_of_deposits_mutex);
pthread_mutex_unlock(&list_of_deposits_mutex);
```

В TCP сервере использовалась структура для создания нового клиента со следующими полями:

```
User info* make new client(int sockfd, int port, char* address, pthread t
     User info* new client = (User info*) malloc(sizeof(User info));
3
4
      new client -> port = port;
5
      new client -> address = address;
6
      new client -> sockfd = sockfd;
7
      new client -> next = NULL;
8
      new client -> client thread = client thread;
9
10
      return new client;
11
```

В UDP сервере использовалась похожая структура для создания нового клиента, но с дополнительными полями:

```
1   new_client -> required_index = 1;
2   new_client -> last_answer = NULL;
3   new_client -> packet_size = 0;
```

При использовании протокола UDP была необходимость в контроле: порядка посылок, дублирования посылок и потери.

Для решения этих проблем в каждый пакет вкладывался номер этого пакета. Для определения, куда отправлять ответ (так как нет выделенного сокета) требовалось хранить историю по каждому соединению. Каждый клиент заносился в структуру данных.

8. Сервис депозитов

8.1. Возможности сервера

- Вывод списка клиентов
- Отключение клиента

- Начисление процентов
- Вывод счета банка
- Вывод всех вкладов
- Завершение работы

8.2. Типы пакетов

```
#define ERROR_PACKET 1

#define ACKNOWLEDGMENT_PACKET 2

#define LIST_OF_DEPOSITS_PACKET 3

#define OPEN_DEPOSIT_PACKET 4

#define REFILL_DEPOSIT_PACKET 5

#define CLOSE_DEPOSIT_PACKET 6

#define GET_LIST_OF_DEPOSITS_PACKET 7

#define GET_BANK_AMOUNT 8

#define SHOW_BANK_AMOUNT 9

#define PLEASE_ADD_PERCENTS 10
```

8.2.1. ERROR PACKET

Посылается сервером, когда не удалось открыть вклад/пополнить вклад/закрыть вклад.

Таблица 8.1

Формат пакета

length	type	text
4	2	4

8.2.2. ACKNOWLEDGMENT PACKET

Посылается сервером в ответ на запрос открытия вклада/пополнения вклада/начиления процентов по вкладам/закрытия вклада.

Таблица 8.2

Формат пакета

length	type	ack_type	deposit_id	initial_amount
4	2	2	4	4

8.2.3. LIST OF DEPOSITS PACKET

Посылается сервером в ответ на запрос списка депозитов.

Таблица 8.3

Формат пакета

leng	gth	type	init_amount	curr_amount	 dep_id	init_amount	curr_amount	
4		2	4	4	 4	4	4	

8.2.4. OPEN DEPOSIT PACKET

Посылается клиентом для открытия депозита.

Таблица 8.4

Формат пакета

length	type	initial_amount
4	2	4

8.2.5. REFILL DEPOSIT PACKET

Посылается клиентом для пополнения депозита.

Таблица 8.5

Формат пакета

length	type	deposit_id	amount
4	2	4	4

8.2.6. CLOSE DEPOSIT PACKET

Посылается клиентом для закрытия депозита.

Таблица 8.6

Формат пакета

length	type	deposit_id
4	2	4

8.2.7. GET LIST OF DEPOSITS PACKET

Посылается клиентом для получения списка своих депозитов.

Таблица 8.7

Формат пакета

length	type
4	2

8.2.8. GET BANK AMOUNT

Посылается клиентом для запроса счета банка.

Таблица 8.8

Формат пакета

length	type

9. Результаты тестирования приложения

9.1. TCP

Было проведено полноценное тестирование и отладка приложения на нескольких клиентах. Пример плана тестирования всего функционала приведен ниже.

После каждой операции на клиенте и сервере появляется меню действий, из которого клиент или сервер выбирает нужный пункт (рис. 9.1. и 9.2.).

- 1) Вывести список клиентов
- 2) Отключить клиента
- 3) Начислить проценты
- 4) Показать счёт банка
- 5) Показать все вклады
- 6) Завершить работу

Рисунок 9.1. Меню сервера

- Открыть вклад
 Посмотреть вклады
- 3) Пополнить вклад
- 4) Закрыть вклад
- 5) Завершить работу
- 6) Показать счет банка
- 7) Начислить проценты по вкладам

1

Enter amount of deposit: 70

You opened deposit with id 1 and amount 70.

Рисунок 9.2. Меню клиента и клиент 1 открыл первый вклад размером 70

1

Enter amount of deposit: 60
You opened deposit with id 2 and amount 60.

Рисунок 9.3. Клиент 2 открыл первый вклад размером 60

1

Enter amount of deposit: 50
You opened deposit with id 3 and amount 50.

Рисунок 9.4. Клиент 1 открыл второй вклад размером 50

2

id of denosit: 1

id of deposit: 1

initial amount of deposit: 70

current amount of deposit: 70.000000

id of deposit: 3

initial amount of deposit: 50

current amount of deposit: 50.000000

CLIENT 4 client disconnected

Process finished with exit code 0

Рисунок 9.17. Сервер отключается и в процессе отключения отключает подключенных клиентов

1
Enter amount of deposit: 30

Process finished with exit code 13

Рисунок 9.18. Клиент пытается взаимодействовать с сервером после его отключения

9.2. UDP

Функционал приложения с использованием UDP не поменялся, поэтому предыдущий план тестирования на TCP и UDP совпал. Для UDP приложения было проведено дополнительное тестирование в виду особенностей протокола.

Сервер и клиент при передаче показывают индекс пакетов для удобства отладки приложения. На рисунке видно, что пакеты отправляются по очереди, ошибки при передаче отсутствуют.

```
1) Начислить проценты
2) Показать счёт банка
3) Показать все вклады
4) Завершить работу
5) Посмотреть список клиентов
6) Удалить вклады клиента

```

Рисунок 9.35. Третий вклад не был создан, так как пакет имел индекс 2

10. Выводы

Был получен опыт разработки клиент-серверного приложения, написания прикладного протокола, работа с транспортными протоколами TCP/UDP. Разработан сервер-банк, в котором был реализован весь функционал согласно исходному заданию.

Для перехода с TCP на UDP необходимо было бы внести следующие изменения в прикладной протокол:

- Контроль очерёдности, потери и дублирования данных
- Необходимость добавления номера пакета в сам пакет

При реализации указанных изменений скорость передачи данных сильно возрастает, что является основным достоинством UDP.

Программирование TCP проще, однако скорость работы с использование UDP выше, так как в UDP отсутствует постоянное соединение между клиентом и сервером.

UDP предоставляет сервис ненадежных дейтаграмм, в отличие от TCP, где присутствует модель рукопожатий для обеспечения надежности, упорядочивания и целостности данных.

В виду отсутствия постоянного соединения реализация сервиса депозитов на UDP была чуть сложнее.

Проблемы потери, дублирования и перемешивания решала система контроля индексов всех посылаемых пакетов, а также система таймаутов и повторной посылки данных.
